

## Cross-correction: Tests of Function 1

Corrected by group: T02

Group we are correcting: T3

We found this possible improvements:

- You should also check the validity of the creation of the json file, check if it is in the correct format.

- According to the presentation for the outputs you must also check the Equivalence Classes, Boundary Values and Exceptions; in this case you're only checking the exceptions.

- You must check if it is his first reservation, if it is not, you must raise an exception. The way we did it was by checking that the ID Card was not beneath the previously introduced ID.

- In the instructions it only appeared a certain amount of exceptions, you added some subgroups beneath them. We would say that there is no problem with that, but we comment on it in case you want to discuss it with your group.

Besides this, we find your tests extremely complete, you seem to be considering the full set of cases.

Suggestion for the Json File creation: As you will have to check that the Reservation made is the first done by the client, it is more optimal to include all your dictionaries with data in the same json file. This way you will be able to move between registrations more easily, and therefore find more easily the information to determine queries like the previously requested.
